091M4041H - Assignment 2 Algorithm Design and Analysis

Song Qige 2017E8018661044 2017年11月17日

1 字符串解码方式(4)

1.1 optimal substructure and DP equation

$$OPT[i] = \begin{cases} OPT[i-1] & msg[i] \ and \ msg[i-1] \ can't \ decode \ together \\ \\ OPT[i-2] + OPT[i-1] & msg[i] \ and \ msg[i-1] \ can \ decode \ together \\ \\ OPT[i-1] & msg[i] = 0 \ and \ msg[i] \ and \ msg[i-1] \ can \ decode \ together \end{cases}$$

OPT[i]表示从msg[1]到msg[i]的序列的解码方式数。 $0 < i < the\ length\ of\ the\ message$

1.2 algorithm describe and pseudo-code

计算OPT[i]处的解码方式时,考虑msg[i]为0和不为0两种情况,如果msg[i]为0,msg[i]必须和msg[i-1]一起解码,此时OPT[i]=OPT[i-1],如果msg[i]必须和msg[i-1]一起解码(不是10或20),则输入字符串有误。如果msg[i]不为0,当msg[i]不能和msg[i-1]一起解码(不在1到26之间)时,

2

OPT[i]=OPT[i-1]。当msg[i]可以和msg[i-1]一起解码时,OPT[i]=OPT[i-1]+OPT[i-2]。

```
1: function WAYSTODECODE(msg[], len)
      if msg[1] == 0 then
2:
          print "input string error!"
3:
       else
 4:
          OPT[1] = 1
 5:
       end if
6:
      if msg[2] can't decode with msg[1] or msg[2] == 0 then
7:
8:
          OPT[2] = 1
       else
9:
          OPT[2] = 2
10:
       end if
11:
       for i=3 \rightarrow len do
12:
          if msg[i] == 0 then
13:
             if msg[i] can't decode with msg[i-1] then
14:
                 print "input string error!"
15:
                 return -1
16:
             else
17:
                 OPT[i] = OPT[i-1]
18:
             end if
19:
          else
20:
             if msg[i] can't decode with msg[i-1] then
21:
                 OPT[i] = OPT[i-1]
22:
```

3

```
23: else
24: OPT[i] = OPT[i-1] + OPT[i-2]
25: end if
26: end if
27: end for
28: return OPT[len]
29: end function
```
